---

The field-dependent magnetization  $m(H, T)$  of 1- and 2-dimensional classical magnets described by the  $D$ -component vector model is calculated analytically in the whole range of temperature and magnetic fields with the help of the  $1/D$  expansion. In the 1-st order in  $1/D$  the theory reproduces with a good accuracy the temperature dependence of the zero-field susceptibility of antiferromagnets  $\chi$  with the maximum at  $T \lesssim |J_0|/D$  ( $J_0$  is the Fourier component of the exchange interaction) and describes for the first time the singular behavior of  $\chi(H, T)$  at small temperatures and magnetic fields:  $\lim_{T \rightarrow 0} \lim_{H \rightarrow 0} \chi(H, T) = 1/(2|J_0|)(1 - 1/D)$  and  $\lim_{H \rightarrow 0} \lim_{T \rightarrow 0} \chi(H, T) = 1/(2|J_0|)$ .

---

KEY WORDS: Low-dimensional magnets; magnetic susceptibility; spherical model;  $1/D$  ( $1/n$ ) expansion.

## 1. Introduction

A great variety of low-dimensional magnetic systems were synthesized and experimentally investigated during the last decades (see, e.g., refs. [1] and [2]). The idealized 1- and 2-dimensional models (without interplane or interchain coupling and anisotropy) are characterized by a strong short-range order in the low-temperature region, whereas the long-range order is ruled out being smeared off by the longwavelength spin waves. Complementary to the high-temperature series expansions (HTSE, see, e.g., refs. [3, 4, 5]), such approaches as the "modified spin wave theory" [6] and the "Schwinger boson mean field theory" [7] were applied to low-dimensional antiferromagnets at low temperatures. These

two methods giving very similar results (with a wrong factor in the antiferromagnetic susceptibility in ref. [7]) are not rigorous expansions in the parameter  $T/|J| \ll 1$  ( $J$  is the exchange integral) but rather some variational approaches. The results break down, however, at  $T \sim |J|$  and thus cannot describe the situation in the whole temperature range. Since the absence of magnetization was introduced in ref. [6] as some additional self-consistency requirement, the generalization for the case with the external magnetic field  $\mathbf{H}$  is a problem.

In ref. [8] an analytical method of calculation of the physical quantities of *classical* low-dimensional magnets in the whole temperature range was proposed, which is based on the  $1/D$  expansion for the model of  $D$ -component classical spin vectors on a lattice [9]:

$$\mathcal{H} = -\mathbf{H} \sum_i \mathbf{m}_i - \frac{1}{2} \sum_{ij} J_{ij} \mathbf{m}_i \mathbf{m}_j \quad |\mathbf{m}| = 1 \quad (1.1)$$

with the help of the diagram technique developed in ref. [10]. For the Heisenberg model ( $D = 3$ ) in the 1-st order in  $1/D$  the calculated temperature dependences of the antiferromagnetic susceptibility and internal energy at  $H = 0$  turn out to be very good, which is shown by the comparison with the MC simulation data [11] for the internal energy of the square lattice (s.l.) classical ferromagnet and with the exact results [12] for a "toy" example of the classical linear chain (l.c.) model. In particular, for both models the characteristic maximum of the antiferromagnetic susceptibility at  $T \lesssim |J_0|/D$  is in contrast to refs. [6] and [7] well reproduced. The reason for the efficiency of the  $1/D$  expansion even for  $D = 3$  is that it yields the exact results for the thermodynamic quantities at  $T \rightarrow 0$  and reproduces several leading terms of their HTSE expansion (see ref. [8]) interpolating thus between these limits in the whole temperature range. The applicability of the approach to classical low-dimensional magnets proposed in ref. [8] is not restricted to the case  $H = 0$ , and it can be applied to the problem of the singular behavior of the antiferromagnetic susceptibility  $\chi^{AF}(H, T)$  at low temperatures and magnetic fields, i.e. the intermutability of its limits  $\lim_{H \rightarrow 0} \lim_{T \rightarrow 0}$  and  $\lim_{T \rightarrow 0} \lim_{H \rightarrow 0}$ , which could not be up to now described by other analytical methods. The physical reason for such a singular behavior is the following. With lowering temperature the system becomes locally ordered, and  $D - 1$  susceptibilities transverse with respect to the local sublattice orientation tend to the value  $1/(2|J_0|)$  ( $J_0 = zJ$ ,  $z$  is the number of nearest neighbors), whereas the longitudinal one tends to zero. At  $H = 0$  there is no preference direction, and the susceptibility of the sample is given by the average over the local sublattice orientations, which results in  $\lim_{T \rightarrow 0} \lim_{H \rightarrow 0} \chi^{AF}(H, T) = 1/(2|J_0|)(1 - 1/D)$ . For the Heisenberg model the  $D$ -dependent factor makes up the well-known number  $2/3$ . To the contrary, for the arbitrary small  $H \neq 0$  at sufficiently low  $T$  the lowest-energy state with the sublattice magnetizations driven perpendicular to the field  $\mathbf{H}$  and tilted in the direction of  $\mathbf{H}$  is realised. In this state the susceptibility takes

up its transverse value:  $\lim_{H \rightarrow 0} \lim_{T \rightarrow 0} \chi^{AF}(H, T) = 1/(2|J_0|)$ . A quantitative description of this effect and the calculation of the magnetization  $m(H, T)$  of low-dimensional classical antiferromagnets in the whole range of temperatures and magnetic fields with the help of the  $1/D$  expansion is the purpose of this work.

The following part of the article is organized as follows. In Section 2 an improved version of the diagrammatic  $1/D$  expansion for classical spin systems with the magnetic field is developed and the results for the magnetization and spin-spin correlation function in the 1-st order in  $1/D$  are obtained. In Section 3 the general  $1/D$ -results, which are double integrals over the Brillouin zone, are calculated analytically and analyzed for the classical linear chain model, for which there is no exact solution in the case with the magnetic field. In Section 4 the results are converted into the form convenient for numerical calculations and the analysis at low temperatures for 2-dimensional systems, and the temperature and magnetic field dependences of the antiferromagnetic susceptibility are represented. In Section 5 some important features of the  $1/D$  expansion and its applicability to the systems with concrete values of  $D$  are discussed.

## 2. The $1/D$ expansion

The physical quantities of ferro- and antiferromagnets described by the hamiltonian (1.1) can be expanded in powers of  $1/D$  with the help of the diagram technique for classical spin systems [8, 10]. Here the consideration of ref. [8] is improved and generalized to the case  $H \neq 0$ . We choose the  $z$  axis along the magnetic field  $\mathbf{H}$ , the other (transverse) components of the spin vector  $\mathbf{m}$  are designated by the index  $\alpha = 1, 2, \dots, D-1$ . The wavevector-dependent transverse susceptibility  $\chi_{\perp}(\mathbf{k}) \equiv \chi_{\alpha}(\mathbf{k})$  of a classical spin system is related to the Fourier-transform of the spin-spin correlation function  $S_{\alpha\alpha}(\mathbf{r} - \mathbf{r}') = \langle m_{\alpha}(\mathbf{r}) m_{\alpha}(\mathbf{r}') \rangle$  via the formula  $\chi_{\perp}(\mathbf{k}) = \beta S_{\alpha\alpha}(\mathbf{k})$ ,  $\beta = 1/T$ . With the help of the diagram technique of ref. [8]  $\chi_{\perp}(\mathbf{k})$  can be represented as

$$\chi_{\perp}(\mathbf{k}) = \frac{\beta \hat{\Lambda}_{\alpha\alpha}(\mathbf{k})}{1 - \hat{\Lambda}_{\alpha\alpha}(\mathbf{k}) \beta J_{\mathbf{k}}} \quad (2.1)$$

where  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$  is the compact (irreducible) part of  $S_{\alpha\alpha}(\mathbf{k})$  given by the diagrams, which cannot be cut by the one interaction line  $\beta J_{\mathbf{k}}$ . For the isotrope systems considered here it is not necessary to write down the diagrams for the magnetization  $m = \langle m_z \rangle$ , because  $m(H)$  can be determined from (2.1). Indeed, in a transverse magnetic field  $H_{\perp} \ll H$  the magnetization  $\mathbf{m}$  is simply rotated on the angle  $\theta = H_{\perp}/H \ll 1$ , which results in the important relation

$$\chi_{\perp} \equiv \chi_{\perp}(0) = m/H. \quad (2.2)$$

The longitudinal susceptibility can be determined now by the formula

$$\chi_z \equiv \partial m / \partial H = \chi_\perp + H(\partial \chi_\perp / \partial H) \quad (2.3)$$

which is much easier than the direct diagrammatic calculation of  $\chi_z(\mathbf{k})$ .

The compact part  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$  in (2.1) can be represented in the 1-st order in  $1/D$  by the diagram set from ref. [8] completed by the additional diagrams for  $H \neq 0$ , which can be estimated and selected according to the same rules. The general principle here is that the diagrams with multiple *irreducible* integrations over wavevectors (i.e. those that do not separate into products of independent simpler integrals) are small as the corresponding powers of  $1/D$ . Thus, in each order in  $1/D$  the complexity of diagrams to be taken into account is restricted: in the zeroth order in  $1/D$  (the spherical model) only diagrams with the one-loop integration over the Brillouin zone survive, and in the 1-st order in  $1/D$  the double integrals over the Brillouin zone appear. The large number of diagrams in the case  $H \neq 0$  necessitates, however, an improvement of the method, which consists in taking into account some diagrams *implicitly* with the subsequent solution of the corresponding equation for  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$ . All the diagrams, which contribute to  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$  in the 1-st order in  $1/D$ , are represented in figs.1,2. Note that the renormalized transverse interaction lines in fig.1 contain the unknown quantity  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$  itself, which means implicitly accounting for the additional class of diagrams of the type 1 and 2 in the fig.3 of ref. [8]. At  $H = 0$  from all the diagrams in fig.2,a survive only the diagrams 1, 2 and 5, and the last term in the Dyson equation for the longitudinal interaction line fig.2,b disappears. The wavevector dependence of  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$  is due to the diagrams 5–8 in fig.2,a. There is one more diagram 7' that is analogous to 7 and is not represented in fig.2,a to save the place. Taking into account only the diagrams in fig.1 results in the self-consistent Gaussian approximation (SCGA), which describes rather good the thermodynamics of 3-dimensional ferromagnets [10]. The analytical form of  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$  in fig.1 reads

$$\hat{\Lambda}_{\alpha\alpha}(\mathbf{k}) = \tilde{\Lambda}_{\alpha\alpha} + \hat{\Lambda}_{\alpha\alpha}^{(1/D)}(\mathbf{k}) \quad (2.4)$$

where  $\hat{\Lambda}_{\alpha\alpha}^{(1/D)}(\mathbf{k})$  is the sum of the diagrams represented in fig.2,a vanishing in the limit  $D \rightarrow \infty$  (see Appendix), and  $\tilde{\Lambda}_{\alpha\alpha}$  is the renormalized 2-spin cumulant average given by [8, 10]

$$\tilde{\Lambda}_{\alpha\alpha} = \frac{1}{\pi^{(D-1)/2}} \int d^{D-1}r \exp(-r^2) \Lambda_{\alpha\alpha}(\boldsymbol{\zeta}). \quad (2.5)$$

Here  $\Lambda_{\alpha\alpha}$  is one of the cumulant spin averages of a general type [8]

$$\Lambda_{\alpha_1\alpha_2\ldots\alpha_p}(\boldsymbol{\xi}) = \frac{\partial^p \Lambda(\boldsymbol{\xi})}{\partial \xi_{\alpha_1} \partial \xi_{\alpha_2} \ldots \partial \xi_{\alpha_p}}, \quad (2.6)$$

obtained through the generating function  $\Lambda(\boldsymbol{\xi}) = \ln Z_0(\boldsymbol{\xi})$ ,

$$Z_0(\boldsymbol{\xi}) = \text{const} \cdot \xi^{-(D/2-1)} I_{D/2-1}(\xi) \quad (2.7)$$

Fig. 1: (a) Diagrams for the compact part  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$  (see also fig.2,a); (b) block summation of transverse loops for the renormalized cumulant one-site 2-spin average  $\hat{\Lambda}_{\alpha\alpha}$ ; (c) Dyson equation for the renormalized transverse interaction.

Fig. 2: (a) Additional  $1/D$ -diagrams for  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$ ; (b) Dyson equation for the renormalized longitudinal interaction; (c) ladder equation for the four-spin correlation line.

is the partition function of the  $D$ -component classical spin,  $I_\nu(\xi)$  is the modified Bessel function,

$$\zeta = \beta(\mathbf{H} + \mathbf{m}J_0) + 2l_\alpha^{1/2}\mathbf{r}, \quad (2.8)$$

$\mathbf{r}$  is the  $(D-1)$ -component vector perpendicular to  $\mathbf{H}$ . The last term in (2.8) describes the Gaussian transverse fluctuations of the molecular field  $\mathbf{H} + \mathbf{m}J_0$  with the dispersion proportional to  $l_\alpha$ , which leads to the renormalization of the cumulant spin averages described by (2.5) for  $\Lambda_{\alpha\alpha}$  and by analogous formulas for the other cumulants entering  $\hat{\Lambda}_{\alpha\alpha}^{(1/D)}(\mathbf{k})$  (dashed ovals in figs.1,2). This renormalization results from the block summation of the all one-loop diagrams with the transverse interaction in fig.1,b; the quantity  $l_\alpha$  is given by the integral over the Brillouin zone

$$l_\alpha = \frac{1}{2} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{\beta J_{\mathbf{q}}}{1 - \hat{\Lambda}_{\alpha\alpha}(\mathbf{q})\beta J_{\mathbf{q}}} \quad (2.9)$$

where  $v_0$  is the unit cell volume ( $v_0 = a_0^d$  for the l.c. ( $d=1$ ) and s.l. ( $d=2$ ),  $a_0$  is the atomic space). The  $(D-1)$ -dimensional integral in (2.5) can be simplified taking advantage of the symmetry with respect to the transverse variables and using the explicit form

$$\Lambda_{\alpha\alpha}(\xi) = \frac{B(\xi)}{\xi} \left(1 - \frac{\xi_\alpha^2}{\xi^2}\right) + B'(\xi) \frac{\xi_\alpha^2}{\xi^2}, \quad (2.10)$$

where

$$B(\xi) = \partial\Lambda(\xi)/\partial\xi = I_{D/2}(\xi)/I_{D/2-1}(\xi) \quad (2.11)$$

is the generalized Langevin function and  $B'(\xi) \equiv dB/d\xi$ . Making in (2.10) the substitution  $\xi_\alpha^2 = \xi_r^2/(D-1)$  with  $\xi_r \equiv 2l_\alpha^{1/2}r$  and in (2.5) the partial integration to get rid of  $B'$ , one obtains

$$\tilde{\Lambda}_{\alpha\alpha} = \frac{2}{\Gamma((D+1)/2)} \int_0^\infty dr r^D \exp(-r^2) \frac{B(\zeta)}{\zeta} \quad \zeta = |\zeta| \quad (2.12)$$

The formulas (2.4), (2.12) and (2.9) yield the integral equation for the compact part of the spin-spin correlation function  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$  entering the basic expression (2.1).

By the expansion in powers of  $1/D$  the quantities  $\tilde{\Lambda}_{\alpha\alpha}$  and  $\hat{\Lambda}_{\alpha\alpha}^{(1/D)}(\mathbf{k})$  in (2.4) give rise to the terms starting from the zero- and the 1-st orders in  $1/D$ , correspondingly, whereas the expansion of all other diagrams neglected here starts from  $1/D^2$ . Before proceeding with the calculations we make a reference to the simplest approach — the mean field approximation (MFA) — in which no diagrams with the integration over wavevectors are taken into account. In this case  $l_\alpha \Rightarrow 0$  and  $\zeta = \xi = \beta(H + mJ_0)$ , and in (2.4)  $\hat{\Lambda}_{\alpha\alpha}^{(1/D)}(\mathbf{k}) \Rightarrow 0$ ,

$\tilde{\Lambda}_{\alpha\alpha} \Rightarrow \Lambda_{\alpha\alpha} \Rightarrow B(\xi)/\xi$ . Now with the use of (2.1) and (2.2) one gets the Curie-Weiss equation  $m = B(\xi)$  for the magnetization  $m$ , which yields the phase transition temperature  $T_C^{MFA} = |J_0|/D$ . The latter has no physical significance for 1- and 2-dimensional magnets but can be used as a temperature scale. It is convenient to introduce the dimensionless temperature  $\theta \equiv T/T_C^{MFA}$ , magnetic field  $h \equiv H/|J_0|$  and susceptibility  $\tilde{\chi} \equiv |J_0|\chi$ . Then the formulas (2.1) and (2.9) can be rewritten as

$$\tilde{\chi}_{\perp}(\mathbf{k}) = \frac{\hat{G}_{\mathbf{k}}}{1 - \nu \hat{G}_{\mathbf{k}} \lambda_{\mathbf{k}}} \quad \tilde{l}_{\alpha} \equiv \frac{l_{\alpha}}{D} = \frac{1}{2\theta} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{\lambda_{\mathbf{q}}}{1 - \nu \hat{G}_{\mathbf{q}} \lambda_{\mathbf{q}}} \quad (2.13)$$

where  $\hat{G}_{\mathbf{k}} \equiv (D/\theta) \hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$ ,  $\nu = \pm 1$  for ferro- and antiferromagnets and  $\lambda_{\mathbf{k}} \equiv J_{\mathbf{k}}/J_0$ . In the integral (2.12) the product  $r^D \exp(-r^2)$  is at large  $D$  sharply peaked at  $r = r_0 = (D/2)^{1/2}$ , whereas  $B(\zeta)/\zeta$  changes slowly with  $r$ . Using the expansion of  $B(\xi)$  (2.11) for  $D \gg 1$  [8] one can write

$$\frac{B(\zeta)}{\zeta} \cong \frac{2}{D} \left( g(x) + \frac{1}{D} \frac{x^2}{1+x^2} g^2(x) \right); \quad g(x) = \frac{1}{1 + (1+x^2)^{1/2}} \quad (2.14)$$

where

$$x \equiv 2\zeta/D = x(\tilde{r}) = \left( 4(h + \nu m)^2/\theta^2 + 8\tilde{l}_{\alpha}\tilde{r}^2 \right)^{1/2}; \quad \tilde{r} \equiv r/r_0 \quad (2.15)$$

and evaluate (2.12) by the pass method. In the 1-st order in  $1/D$  for  $\tilde{G} \equiv (D/\theta)\tilde{\Lambda}_{\alpha\alpha}$  one gets

$$\tilde{G} = \frac{2}{\theta} \frac{1}{1 + [1 + 4(h + \nu m)^2/\theta^2 + 8\tilde{l}_{\alpha}]^{1/2}} + \frac{1}{D} \Delta^{(G)} \quad (2.16)$$

where

$$\Delta^{(G)} = \frac{2}{\theta} \left( \frac{x^2}{1+x^2} g^2(x) + \frac{1}{4} \frac{\partial g}{\partial \tilde{r}} + \frac{1}{4} \frac{\partial^2 g}{\partial \tilde{r}^2} \right)_{|\tilde{r}=1} \quad (2.17)$$

is the  $1/D$  correction to the Gaussian integral (2.12) and the derivatives of  $g$  are calculated with the use of (2.14) and (2.15). The 1-st term of (2.16) also contains the  $1/D$  corrections due to the corresponding corrections to  $m$  and  $\tilde{l}_{\alpha}$ .

Before further proceeding with the  $1/D$  expansion we consider at first the limiting case  $D \rightarrow \infty$  corresponding to the spherical model [13]. In this case the quantity  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$  in (2.4) can be neglected, and one can replace in (2.13)  $\hat{G}_{\mathbf{k}}, \hat{G}_{\mathbf{q}} \Rightarrow G$ , where  $G = G(m_0, \tilde{l}_{\alpha 0})$  is given by the 1-st term of (2.16) with the zero-order quantities  $m_0$  and

$$\tilde{l}_{\alpha 0} = \frac{P(G) - 1}{2\theta G}; \quad P(G) = v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{1}{1 - G\lambda_{\mathbf{q}}} \quad (2.18)$$

Here for the square lattice with the n.n. interaction the lattice integral  $P(G)$  is given by  $P(G) = (2/\pi) \mathbf{K}(k)$  with  $k = G$ ,  $\mathbf{K}(k)$  being the elliptic integral of the

1-st kind, and for the linear chain  $P(G) = 1/(1 - G^2)^{1/2}$ . For bipartite lattices considered here the integral  $P(G)$  is the same for ferro- and antiferromagnets and independent of the sign of  $G$ . For this reason the sign-factor  $\nu$  is dropped in the definition of  $P(G)$  (2.18). Note that for 1- and 2-dimensional systems  $P(G)$  diverges for  $G \rightarrow 1$ , which is the reason for the absence of the long-range order. Eliminating now  $\tilde{l}_{\alpha 0}$  and using (2.2) in the form

$$\frac{m_0}{h} = \frac{G}{1 - \nu G} \quad (2.19)$$

one comes to the equation of state of the spherical model:

$$\theta G P(G) = 1 - m_0^2; \quad (2.20)$$

which for  $h \neq 0$  should be solved together with (2.19) (in the general case numerically). For low-dimensional antiferromagnets ( $\nu = -1$ ) at low temperatures ( $\theta \ll 1$ ) in the field region where  $m_0^2 < 1$  the equation (2.20) requires  $G \cong 1$  and  $P(G) \gg 1$ . For the square-lattice model for  $P$  and its derivative this implies

$$\begin{aligned} P(G) &\cong \frac{1}{\pi} \ln \left( \frac{8}{1 - G} \right) \cong \frac{1 - m_0^2}{\theta} \\ P'(G) &\cong \frac{1}{\pi} \frac{1}{1 - G} \cong \frac{1}{8\pi} \exp \left[ \frac{\pi(1 - m_0^2)}{\theta} \right] \end{aligned} \quad (2.21)$$

i.e. the deviation of  $G$  from unity is exponentially small:

$$G \cong 1 - 8 \exp \left[ -\frac{\pi(1 - m_0^2)}{\theta} \right] \quad (2.22)$$

For the linear chain model the corresponding result reads  $1 - G \cong \theta^2/[2(1 - m_0^2)^2]$ . Now with the help of (2.19) one gets for the magnetization  $m_0 \cong h/2$  with only exponentially small corrections in the 2-dimensional case due to (2.22). The latter is valid up to the magnetization saturation point  $h = 2$  (i.e.  $H = 2|J_0|$ ), which corresponds to the spin-flip field of 3-dimensional antiferromagnets. For the fields  $h > 2$  according to (2.19) and (2.20)  $m_0 \cong 1$  and  $G < 1$ :

$$m_0 \cong 1 - (\theta/2)GP(G); \quad G \cong 1/(h - 1) \quad (2.23)$$

In the zero field case the antiferromagnetic susceptibility  $\tilde{\chi} = \tilde{\chi}_\perp = \tilde{\chi}_z = G/(1 + G)$  monotonously decreases with rising temperature from the value  $1/2$  at  $T = 0$  to  $0$  at  $T \rightarrow \infty$ , i.e. the spherical model does not describe the maximum of the antiferromagnetic susceptibility at  $\theta \lesssim 1$ .

Now, returning to the  $1/D$  expansion, one can express the  $1/D$ -correction term  $\Delta^{(G)}$  in (2.16) through the variables of the spherical approximation:

$$\Delta^{(G)} = 2G \left[ \frac{y - 1}{2y - 1} - \frac{P - 1}{2(2y - 1)^2} - \frac{(P - 1)^2(3y - 1)}{(2y - 1)^3} \right]; \quad y \equiv \frac{1}{\theta G} \quad (2.24)$$

and represent the unknown quantities  $m$ ,  $\tilde{l}_\alpha$  and  $\hat{G}_\mathbf{k}$  (see (2.13)) in the form

$$\begin{aligned} m &\cong m_0 + m_1/D \\ \tilde{l}_\alpha &\cong \tilde{l}_{\alpha 0} + \tilde{l}_{\alpha 1}/D \\ \hat{G}_\mathbf{k} &\cong G + \Delta G_\mathbf{k}/D \end{aligned} \quad (2.25)$$

Here the corrections  $m_1$  and  $\tilde{l}_{\alpha 1}$  can be expressed through  $\Delta \hat{G}_\mathbf{k}$  with the use of (2.13) and the relation  $m/h = \tilde{\chi}_\perp(0) = \hat{G}_0/(1 - \nu \hat{G}_0)$ , which results in

$$\frac{m_1}{h} = \frac{\Delta G_0}{(1 - \nu G)^2} \quad (2.26)$$

and

$$\tilde{l}_{\alpha 1} = \frac{1}{2\theta} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{\lambda_\mathbf{q}^2 \Delta G_\mathbf{q}}{(1 - \nu G \lambda_\mathbf{q})^2} \quad (2.27)$$

Expanding now the 1-st term of (2.16) up to the 1-st order in  $m_1$  and  $\tilde{l}_{\alpha 1}$ , one comes to the  $1/D$  part of the equation (2.4) in the dimensionless form

$$\Delta G_\mathbf{k} + \frac{m_0}{\nu h} \frac{2m_0^2 y}{2y-1} \Delta G_0 + \frac{G^2}{2y-1} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{\lambda_\mathbf{q}^2 \Delta G_\mathbf{q}}{(1 - \nu G \lambda_\mathbf{q})^2} = \Delta^{(G)} + \Delta_\mathbf{k}^{(1/D)}, \quad (2.28)$$

where the quantity  $\Delta_\mathbf{k}^{(1/D)}$  is the nonvanishing in the limit  $D \rightarrow \infty$  part of  $D \cdot (D/\theta) \hat{\Lambda}_{\alpha\alpha}^{(1/D)}(\mathbf{k})$  (see Appendix). The solution of the integral equation (2.28) has the form

$$\Delta G_\mathbf{k} = \Delta G_0 + M_\mathbf{k} \quad (2.29)$$

where

$$M_\mathbf{k} = \Delta_\mathbf{k}^{(1/D)} - \Delta_0^{(1/D)} \quad (2.30)$$

and  $\Delta G_0$  is given by

$$\begin{aligned} \Delta G_0 = & \left\{ (2y-1)(\Delta^{(G)} + \Delta_0^{(1/D)}) - G^2 v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{\lambda_\mathbf{q}^2 M_\mathbf{q}}{(1 - \nu G \lambda_\mathbf{q})^2} \right\} \cdot \\ & \left\{ GP' + P(G) + \frac{2m_0^2 y}{1 - \nu G} \right\}^{-1} \end{aligned} \quad (2.31)$$

where  $P' \equiv dP(G)/dG$ . Now, calculating the quantity  $\Delta_\mathbf{k}^{(1/D)}$  (see Appendix) and introducing the function

$$r_\mathbf{q} = v_0 \int \frac{d\mathbf{p}}{(2\pi)^d} g_\mathbf{p} g_{\mathbf{p}-\mathbf{q}}; \quad g_\mathbf{p} \equiv \frac{1}{1 - \nu G \lambda_\mathbf{p}} \quad (2.32)$$

one arrives after numerous cancellations at the final results for  $\Delta G_0$  and  $M_\mathbf{k}$ :

$$\begin{aligned} \Delta G_0 = 2G & \left\{ 1 - [GP' + P + 2m_0^2 y] v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{g_\mathbf{q}}{\tilde{r}_\mathbf{q}} + m_0^2 y v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{g_\mathbf{q}^2}{\tilde{r}_\mathbf{q}} \right. \\ & \left. + \frac{G}{2} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{r'_\mathbf{q}}{\tilde{r}_\mathbf{q}} \right\} \left\{ GP' + P + \frac{2m_0^2 y}{1 - \nu G} \right\}^{-1} \end{aligned} \quad (2.33)$$

and

$$M_{\mathbf{k}} = 2G v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{g_{\mathbf{q}} - g_{\mathbf{q}-\mathbf{k}}}{\tilde{r}_{\mathbf{q}}} \quad (2.34)$$

where  $\tilde{r}_{\mathbf{q}} \equiv r_{\mathbf{q}} + 2m_0^2 y g_{\mathbf{q}}$  and  $r'_{\mathbf{q}} \equiv \partial r_{\mathbf{q}} / \partial G$ . The similar results obtained earlier [14, 15] by another method for the particular ferromagnetic case were used for the investigation of the phase transition in 3-dimensional ferromagnets. It is interesting to note that the function  $r_{\mathbf{q}}$  (2.32) is (like  $P(G)$ ) identical for ferro- and antiferromagnets and has a singularity at  $G \rightarrow 1$  and  $\mathbf{q} \rightarrow 0$ . In contrast, the quantity  $\tilde{r}_{\mathbf{q}}$  entering (2.33) and (2.34) has for antiferromagnets one more singularity at  $G \rightarrow 1$  and  $\mathbf{q} \rightarrow \mathbf{b}$  ( $\mathbf{b}$  is the inverse lattice vector) due to  $g_{\mathbf{q}}$ , which disappears, however, in zero magnetic field ( $m_0 = 0$ ). This is a formal mechanism responsible for the singular behavior of the susceptibility  $\chi(H, T)$  of the low-dimensional antiferromagnets in the limit  $H, T \rightarrow 0$  discussed in the Introduction.

Before proceeding with the application of the results obtained to the concrete systems it is worth to note some general properties of the  $\mathbf{k}$ -dependent spin-spin correlation function (see (2.1) and (2.13)) that can essentially simplify the consideration in the low-temperature range. In particular, for 2-dimensional ferromagnets in the spherical limit the quantity  $G$  (2.22) is exponentially close to unity at  $h = 0$  and low temperatures, which implies exponentially small gap in the spin-wave spectrum. Since this property cannot be changed with taking into account  $1/D$  corrections, the quantity  $\Delta G_0$  in (2.29) should be also exponentially small. This is physically clear and can be confirmed by the direct analysis [8] of the results obtained. On the other hand, the  $\mathbf{k}$ -dependent contribution  $M_{\mathbf{k}}$  in (2.29) has not to be exponentially small at low temperatures and  $\mathbf{k} \neq 0$ . In fact, the value  $M_{\mathbf{b}}$  determines the  $1/D$  correction to the *antiferromagnetic* susceptibility in zero magnetic field [8], which can be expanded in powers of  $\theta \ll 1$ . Thus, by calculation of such quantities of 2-dimensional magnetic systems at low temperatures, which are not exponentially small, one can use only the quantity  $M_{\mathbf{k}}$  (2.34), being much simpler than the expression for  $\Delta G_0$  (2.33). This means that only  $\mathbf{k}$ -dependent diagrams for the compact part of the spin-spin correlation function  $\hat{\Lambda}_{\alpha\alpha}(\mathbf{k})$  should be taken into account in the low-temperature range, which is a clear advantage of the diagrammatic  $1/D$  expansion in comparison with the earlier version [14, 15]. The considerations above can be extended also on 2-dimensional *antiferromagnets* at low temperatures in the field region  $h < 2$  ( $H < 2|J_0|$ ), where the magnon gap is exponentially small. Here the quantity  $\hat{G}_{\mathbf{b}}$  in (2.13) should be exponentially close to unity in all orders in  $1/D$ . Consequently, the quantity  $\Delta G_0$  contributing to the magnetization and susceptibility of an antiferromagnet (see (2.26)) is given according to (2.29) by  $\Delta G_0 = \Delta G_{\mathbf{b}} - M_{\mathbf{b}} \cong -M_{\mathbf{b}}$ . In the next sections we apply the results of the 1-st order in  $1/D$  obtained above to the analysis of the equation of state  $m(H, T)$  of 1- and 2-dimensional classical antiferromagnets.

### 3. The linear chain classical spin model

For the linear chain model  $\lambda_k \equiv J_k/J_0 = \cos(a_0 k)$ , and the integrals (2.32) and (2.33) can be calculated analytically. One gets  $r_q = 2P(G)/(2 - G^2 - G^2\lambda_q)$  with  $P(G) = 1/(1 - G^2)^{1/2}$  and

$$\Delta G_0 = \frac{2G(1 - m_0^2)(1 - G^2)^{3/2}}{1 + m_0^2 + 2m_0^2\nu G} \left\{ 1 + \frac{3}{2}P(G) - \frac{5 + 3m_0^2 - 2m_0^2G^2}{2[1 + m_0^2(1 - G^2)]}F \right. \\ \left. + \frac{1}{2} \frac{1 - F}{1 - m_0^2(1 - \nu G)} \left[ \frac{1 - m_0^2}{1 - G^2}(1 - \nu G) - 3(1 - m_0^2) - 2\nu G m_0^2 \right] \right\} \quad (3.1)$$

where

$$F = \frac{1 + m_0^2(1 - G^2)}{[(1 + m_0^2)^2(1 - G^2) + 2G^2m_0^2(1 - m_0^2)(1 - \nu G)]^{1/2}} \quad (3.2)$$

The magnetization  $m_0$  and the parameter  $G$  of the spherical model in (3.1) and (3.2) are given by the solution of (2.19) and (2.20). It can be shown that in zero magnetic field the results for the susceptibility  $\chi$  are equivalent to those obtained by the expansion of the exact solution [12] up to the 1-st order in  $1/D$ . In the low field and temperature limit  $h, \theta \ll 1$  one has  $m_0 \cong h/2 \ll 1$ ,  $G \cong 1 - \theta^2$  and hence  $F \cong (h^2 + \theta^2)^{-1/2} \gg 1$ . Taking into account the leading contribution into  $\Delta G_0$  given by the 1-st term in square brackets, one gets with the use of (2.25) and (2.26) the following result

$$\tilde{\chi}_\perp = \frac{m}{h} = \frac{1}{2} \left[ 1 + \frac{1}{D} \left( -\frac{\theta}{(h^2 + \theta^2)^{1/2}} + \theta + O(\theta^2) \right) \right] \quad (3.3)$$

It can be seen that for  $h = 0$  the susceptibility  $\tilde{\chi}_\perp$  decreases with lowering temperature due to the term  $\theta$  in (3.3) and attains the value  $\tilde{\chi}_\perp = (1/2)(1 - 1/D)$  at  $\theta = 0$ . If  $h \neq 0$ , then at  $\theta = h^{2/3}$  the value of  $\tilde{\chi}_\perp$  attains a minimum and then rises to  $1/2$  at  $\theta = 0$ . Note that the singular term in (3.3) becomes of order unity at  $\theta \sim h \ll h^{2/3}$ , which is one more characteristic temperature. Such a qualitative behavior of the susceptibility of a low-dimensional classical antiferromagnet is in accord with the physical considerations made in the Introduction. The longitudinal susceptibility  $\tilde{\chi}_z$  calculated with the help of (2.3) and (3.3) has the form

$$\tilde{\chi}_z = \frac{\partial m}{\partial h} = \frac{1}{2} \left[ 1 + \frac{1}{D} \left( -\frac{\theta^3}{(h^2 + \theta^2)^{3/2}} + \theta + O(\theta^2) \right) \right] \quad (3.4)$$

This expression has the minimum at  $\theta \cong 3^{1/3}h^{2/3} \gg h$ , and also the maximum at  $\theta \cong 3^{-1/2}h^{3/2} \ll h$  (the 3-rd characteristic temperature) where  $\tilde{\chi}_z \cong 1/2 + (2/D)(h/3)^{3/2} > 1/2$ . The susceptibilities  $\tilde{\chi}_\perp(h, \theta)$  and  $\tilde{\chi}_z(h, \theta)$  are represented as functions of temperature for some field values in figs.3,4.

An interesting feature of the susceptibility  $\tilde{\chi}_z$  manifests itself in the  $1/D$  approximation in the low temperature limit ( $\theta \ll 1$ ) in the vicinity of the

Fig. 3: Temperature dependences of the transverse susceptibility  $\tilde{\chi}_\perp = m/h$  of the l.c. Heisenberg antiferromagnet for different magnetic fields in the 1-st order in  $1/D$ .

Fig. 4: Temperature dependences of the longitudinal susceptibility  $\tilde{\chi}_z = \partial m / \partial h$ .

magnetization saturation point  $h = 2$  (i.e.  $H = H_c \equiv 2|J_0|$ ). In the spherical limit, adopting  $m_0 = 1 - \delta m_0$  and  $G = 1 - \delta G$  with  $\delta m_0, \delta G \ll 1$ , one can simplify the equations (2.19) and (2.20) for the linear chain antiferromagnet to  $\theta/(2\delta G)^{1/2} = 2\delta m_0$  and  $2\delta m_0 - \delta G = 2 - h$ , which results in the following equation for  $\delta m_0$  in the scaled form

$$x - 1/(16x^2) = x_0; \quad x \equiv \delta m_0/\theta^{2/3}; \quad x_0 \equiv (2 - h)/(2\theta^{2/3}) \quad (3.5)$$

This equation describes the temperature-induced rounding of the transition between the dependences  $m_0 \cong h/2$  and  $m_0 \cong 1$  in the small field interval  $|2 - h| \sim \theta^{2/3}$ . Now, the  $1/D$  correction  $m_1$  determined for  $|2 - h|, \theta \ll 1$  from (2.26) and (3.1), (3.2) has the form

$$m_1 \cong \delta m_0(3 - 3Y^{-1/2} + Y^{1/2})/Y; \quad Y \equiv 1 + \delta m_0/\delta G = 1 + 8x^3 \quad (3.6)$$

where  $x$  is the solution of (3.5). In the limiting cases one gets from (3.7) and (3.6) for the magnetization  $m = m_0 + m_1/D$  the following results

$$m \cong \begin{cases} \frac{h}{2} + \frac{1}{D} \frac{\theta}{2(2-h)^{1/2}} - \frac{\theta^2}{[2(2-h)]^2}; & \theta^{2/3} \ll 2-h \ll 1 \\ 1 - \left(\frac{\theta}{4}\right)^{2/3} \left[1 - \frac{1}{D} \left(\frac{2}{3}\right)^{1/2} (6^{1/2}-1)\right]; & h = 2 \\ 1 - \frac{\theta}{[8(h-2)]^{1/2}} \left(1 - \frac{1}{D}\right); & \theta^{2/3} \ll h-2 \ll 1 \end{cases} \quad (3.7)$$

It can be seen from (3.7) that in the field region below the saturation point  $h = 2$  the temperature-dependent correction to  $m$  is positive. Accordingly, the susceptibility  $\tilde{\chi}_z = \partial m / \partial h$  is greater than  $1/2$  in this region, but the effect is not great. With the use of (3.6) one can show that for  $D = 3$   $\tilde{\chi}_{z,max} = 0.518$  at  $2 - h = 2.80 \cdot \theta^{2/3}$ . The field dependences of the normalized susceptibility  $\tilde{\chi}_z$  of the 1-dimensional classical antiferromagnet are represented for different temperatures in fig.5. It is interesting to note that a qualitatively similar field dependence of the susceptibility with a logarithmic singularity at small fields was found in ref. [16] for the *quantum* linear chain Heisenberg antiferromagnet with  $S = 1/2$  at  $T = 0$ . There are no physical comments to this effect in ref. [16], but it seems now rather clear that the origin of this low-field singularity of a quantum antiferromagnet is also the orientation of sublattices perpendicular to the field, the quantum effects playing here the role of some "residual temperature".

## 4. The square-lattice classical antiferromagnet

For 2-dimensional lattice the integrals in  $\Delta G_0$  (2.33) cannot be calculated analytically. For the convenience of the analysis at low temperatures and numerical

Fig. 5: Field dependences of the longitudinal susceptibility of the l.c. classical Heisenberg antiferromagnet for different temperatures.

calculations we introduce instead of the strongly singular  $r_{\mathbf{q}}$  (2.32) the weak-singular function [8]

$$\psi_{\mathbf{q}} \equiv \frac{1}{G} v_0 \int \frac{d\mathbf{p}}{(2\pi)^d} \frac{\lambda_{\mathbf{q}} - G\lambda_{\mathbf{p}}\lambda_{\mathbf{p}-\mathbf{q}}}{(1 - G\lambda_{\mathbf{p}})(1 - G\lambda_{\mathbf{p}-\mathbf{q}})} = \frac{1}{G^2} [2P(G) - 1 - (1 - G\lambda_{\mathbf{q}})r_{\mathbf{q}}] \quad (4.1)$$

in which the divergences of the integrand at  $\mathbf{p} = 0$  and  $\mathbf{p} = \mathbf{q}$  at  $G \cong 1$  are partially compensated by the nullification of the numerator. In the longwavelength region the function  $\psi_{\mathbf{q}}$  has the form [8]:

$$\psi_{\mathbf{q}} \cong \begin{cases} \frac{2}{\pi} \ln \frac{8}{1-G} - 1 - \frac{1}{\pi}; & x \equiv (a_0 q)^2 \ll 1 - G \\ \frac{2}{\pi} \ln \frac{8}{x}; & 1 - G \ll x \ll 1 \end{cases} \quad (4.2)$$

and its derivative  $\psi'_{\mathbf{q}} \equiv \partial\psi_{\mathbf{q}}/\partial G$  is given by

$$\psi'_{\mathbf{q}} \cong \begin{cases} \frac{2}{\pi} \frac{1}{1-G}; & x \ll 1 - G \\ -\frac{2}{\pi x} \ln \frac{x}{1-G}; & 1 - G \ll x \ll 1 \end{cases} \quad (4.3)$$

At low temperatures at the corners of the Brillouin zone  $\psi_{\mathbf{q}} = -1 + O(1 - G)$ . In terms of  $\psi_{\mathbf{q}}$  the function  $\Delta G_0$  (2.33) can be written as

$$\begin{aligned} \Delta G_0 = 2G & \left\{ (1-\nu) \frac{GP' + P + 3m_0^2 y}{2y-1} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{1}{1 - a\psi_{\mathbf{q}}} \frac{G\lambda_{\mathbf{q}}}{1 + \bar{G}_{\mathbf{q}}\lambda_{\mathbf{q}}} \right. \\ & + \frac{G}{2} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{a\psi'_{\mathbf{q}}}{1 - a\psi_{\mathbf{q}}} \frac{1 + G\lambda_{\mathbf{q}}}{1 + \bar{G}_{\mathbf{q}}\lambda_{\mathbf{q}}} - \frac{3y-1}{2y-1} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{1}{1 - a\psi_{\mathbf{q}}} \frac{1 + G\lambda_{\mathbf{q}}}{1 + \bar{G}_{\mathbf{q}}\lambda_{\mathbf{q}}} \\ & \left. + \frac{3}{2} + P(G) - \frac{1}{2} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{1}{1 + \bar{G}_{\mathbf{q}}\lambda_{\mathbf{q}}} \right\} \left\{ GP' + P(G) + \frac{2m_0^2 y}{1 - \nu G} \right\}^{-1} \end{aligned} \quad (4.4)$$

where  $y \equiv 1/(\theta G)$ ,  $a \equiv G^2/(2y-1)$  and

$$\bar{G}_{\mathbf{q}} \equiv G \left[ 1 - \frac{2(1-\nu)m_0^2 y}{(2y-1)(1 - a\psi_{\mathbf{q}})} \right] \quad (4.5)$$

For the quantity  $M_{\mathbf{k}}$  (2.34) one gets in a similar way

$$M_{\mathbf{k}} = \frac{2G}{2y-1} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{(1 - G^2\lambda_{\mathbf{q}}^2)(g_{\mathbf{q}} - g_{\mathbf{q}-\mathbf{k}})}{(1 - a\psi_{\mathbf{q}})(1 + \bar{G}_{\mathbf{q}}\lambda_{\mathbf{q}})} \quad (4.6)$$

Putting  $\mathbf{k} = \mathbf{b}$  in (4.6) in the antiferromagnetic case ( $\nu = -1$ ) and taking into account only the exponentially great terms with  $P'(G)$  in  $\Delta G_0$  (4.4) at low temperatures in the field range  $h < 2$ , one arrives at the result

$$\Delta G_0 \cong -M_{\mathbf{b}} = 4a v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \frac{1}{1 - a\psi_{\mathbf{q}}} \frac{\lambda_{\mathbf{q}}}{1 + \bar{G}_{\mathbf{q}}\lambda_{\mathbf{q}}} \quad (4.7)$$

which confirms the conjecture made at the end of Section 2. Since at  $\theta \ll 1$  the quantity  $a \cong (\theta/2)/(1 - \theta/2) \ll 1$  and due to (4.2) the functions  $\psi_{\mathbf{q}}^n$  are integrable ones, one can expand (4.7) in powers of  $a\psi_{\mathbf{q}}$  and then of  $\theta$  to get the development of the  $1/D$  correction to the magnetization  $m_1$  (2.26) at low temperatures. In the lowest order in  $\theta$  one gets

$$m_1 = \frac{h\theta}{2} \frac{1 - P(\bar{G})}{1 - 2m_0^2} \quad (4.8)$$

where  $\bar{G} \cong G(1 - 2m_0^2)$  and  $m_0 \cong h/2$ . This correction is negative for  $h < 2^{1/2}$  and positive for  $2^{1/2} < h \lesssim 2$ . In the case  $h \neq 0$  the quantity  $1 - \bar{G}$  can be interpreted as proportional to the field-induced gap of the out-of-plane spin waves, which makes the lattice integral  $P(\bar{G})$  in (4.8) not divergent at low temperatures. The more detailed physical interpretation of the spin wave dynamics in low-dimensional magnets requires, however, the dynamical generalization of the diagram technique used here. In the small field region, where  $\bar{G} \cong 1$ , with the help of (2.25) and (2.2) in the 1-st order in  $1/D$  one gets

$$\tilde{\chi}_{\perp} = \frac{m}{h} = \frac{1}{2} \left[ 1 + \frac{1}{D} \left( -\frac{\theta}{\pi} \ln \left( \frac{8}{1 - G + h^2/2} \right) + \theta + O(\theta^2) \right) \right] \quad (4.9)$$

where  $G$  is given by (2.22). In the case  $h = 0$  the  $\ln$ -term in (4.9) is identically equal to  $-1$ , and  $\tilde{\chi}_\perp \rightarrow (1/2)(1 - 1/D)$  in the limit  $\theta \rightarrow 0$ . For a whatever small field  $h \neq 0$  this term goes to zero with  $\theta \rightarrow 0$ , and  $\tilde{\chi}_\perp \rightarrow 1/2$ . The transition to the regime, where the magnetic field exerts the influence on the susceptibility of a 2-dimensional antiferromagnet, is sharp due to the strong exponential temperature dependence of  $G$  (2.22) and occurs at the temperature

$$\theta \cong \theta^* = \frac{\pi}{2 \ln(4/h)} \quad (4.10)$$

Note that the value of  $\theta^*$  is for  $h \ll 1$  much larger than the corresponding characteristic temperatures in the 1-dimensional case. The longitudinal susceptibility of the s.q. classical antiferromagnet has the form

$$\tilde{\chi}_z = \frac{1}{2} \left[ 1 + \frac{1}{D} \left( -\frac{\theta}{\pi} \ln \left( \frac{8}{1 - G + h^2/2} \right) + \frac{\theta}{\pi} \frac{h^2}{1 - G + h^2/2} + \theta + O(\theta^2) \right) \right] \quad (4.11)$$

where the additional in comparison to (4.9) term is not very essential at low fields in contrast to the 1-dimensional case (see (3.4)). The temperature dependences of  $\tilde{\chi}_\perp$  and  $\tilde{\chi}_z$  in the magnetic field obtained by the numerical solution of the equations (2.19) and (2.20) and the numerical integration in (4.4) are represented in figs.6 and 7.

The  $1/D$  correction to the magnetization (4.8) increases with approaching the magnetization saturation point  $h = 2$  since here  $\tilde{G} \cong -1$  and  $P(\tilde{G}) \gg 1$ . But the formula (4.8) becomes insufficient in this region, because in (4.4) the integral with  $\psi'_\mathbf{q}$  (see (4.3)) becomes for  $\tilde{G} \cong -1$  comparable with the one with  $P'(\tilde{G})$  due to the great longwavelength contribution, and one should use the complicated analytical expression for  $\psi'_\mathbf{q}$  for  $x \sim 1 - G$  [8]. In contrast, the quantity  $a\psi_\mathbf{q}$  in the denominators in (4.4) and (4.5) can be neglected in the whole field region, since in the low-temperature range  $a\psi_0 \cong \theta P(\tilde{G}) \cong 1 - m_0^2$ . In the field region above the saturation point ( $h > 2$ ) at low temperatures  $m_0 \cong 1$  and in (4.5)  $\tilde{G}_\mathbf{q} \cong -G$ . Neglecting the terms  $\theta P' \ll 1$  in  $\Delta G_0$  (4.4), with the use of (2.23) for the total magnetization  $m = m_0 + m_1/D$  one gets

$$m \cong 1 - \frac{\theta}{2} \left( 1 - \frac{1}{D} \right) GP(G); \quad G \cong \frac{1}{h-1} \quad (h > 2, \theta \ll 1) \quad (4.12)$$

This result is the exact expression for the leading correction to the magnetization of a classical antiferromagnet in the spin-flip phase ( $H > 2|J_0|$ ) in the low-temperature limit, which can be obtained independently with the help of the lowest-order spin wave theory. In the framework of the diagram technique for classical spin systems used here this corresponds to taking into account only the simplest diagram for the magnetization  $m$  with one integration over the Brillouin zone (i.e. the one analogous to the 2-nd diagram in fig.1,b). The derivation of the formula (4.12) is trivial, because the ground state of the system has no

Fig. 6: Temperature dependences of the transverse susceptibility of the s.l. classical Heisenberg antiferromagnet for different magnetic fields in the 1-st order in  $1/D$ .

Fig. 7: Temperature dependences of the longitudinal susceptibility.

spontaneous symmetry breaking and the magnon spectrum has a gap. However, with the approach to  $h = 2$  in (4.12)  $G \rightarrow 1$  and for low-dimensional systems the temperature correction to  $m$  diverges. In the region  $h < 2$  the situation becomes complicated, and to obtain finite results for the thermodynamic quantities one has to take into account some infinite series of diagrams, which is exemplified by the  $1/D$  expansion described above. With the help of (4.8) and (4.12) one can write down the expressions for the magnetization of the 2-dimensional antiferromagnet on both sides of the magnetization saturation point  $h = 2$  excluding a small intermediate region:

$$m \cong \begin{cases} \frac{h}{2} + \frac{\theta}{\pi D} \ln \frac{4}{2-h}; & \theta \ln \frac{1}{\theta} \ll 2-h \ll 1 \\ 1 - \frac{\theta}{2\pi} \left(1 - \frac{1}{D}\right) \ln \frac{8}{h-2}; & \theta \ln \frac{1}{\theta} \ll h-2 \ll 1 \end{cases} \quad (4.13)$$

The latter results are analogous to those for the linear chain model (3.7) that could be also obtained in the same way like here. The normalized susceptibility  $\tilde{\chi}_z$  of the 2-dimensional antiferromagnet is greater than  $1/2$  below the saturation point  $h = 2$ , too, and the maximal value of  $\tilde{\chi}_z$  is greater than that for the linear chain (see fig.8). The latter can be explained by the fact that for a square lattice there is no competing *negative* contribution to  $m$  of the zeroth order in  $1/D$ , as is the case for the linear chain (see (3.7)).

## 5. Discussion

In this article the  $1/D$  expansion of the physical quantities of low-dimensional classical  $D$ -vector models in the whole range of temperatures and magnetic fields was developed, the results obtained being valid for both ferro- and antiferromagnets. For the calculation of the susceptibility and the field-induced magnetization of ferromagnets at low temperatures the method is, however, not very efficient, because these quantities are singular at  $T \rightarrow 0$ . In ref. [8] was shown that at low temperatures the  $1/D$  correction to the susceptibility of a 2-dimensional ferromagnet becomes greater than its value in the zeroth order in  $1/D$ , which means that  $D$  enters the argument of the exponentially great expression for  $\chi \propto 1/(1 - \hat{G}_0)$  (comp. (2.21)). This is in accord with the results of the RG-approach of ref. [17], but does not allow to obtain accurate results in the framework of the  $1/D$  expansion.

On the other hand, the  $1/D$  expansion proves to be a very good instrument for the description of *noncritical* characteristics of low-dimensional magnets, such as the magnetization and susceptibility of antiferromagnets and the energy and heat capacity of both ferro- and antiferromagnets. For the latter the zero-field results (identical in both cases) were obtained in ref. [8], and their generalization to the case with the magnetic field with the use of the methods developed here makes no difficulties. The most remarkable feature of the results

Fig. 8: Field dependences of the longitudinal susceptibility of the s.l. classical Heisenberg antiferromagnet for different temperatures.

obtained with the help of the  $1/D$  expansion is that they describe the maximum in the temperature dependence of the zero-field antiferromagnetic susceptibility and its singular behavior at  $H, T \rightarrow 0$ . The former is the result of taking into account the diagrams with *double* integrations over the Brillouin zone, which was not made in any of the preceding theories. This means allowing for the wavevector dependence of the compact part of the spin-spin correlation function (2.1) as well, or, in the other words, going beyond the Ornstein-Zernike form for  $\chi_{\mathbf{k}}$ . It is worth noting, however, that at low temperatures ( $\theta \ll 1$ ) the results simplify to some expression with only *one* integration over the Brillouin zone (see (4.8)) which corresponds to taking into account the out-of-plane magnons having the field-dependent gap.

An intriguing property of the  $1/D$  expansion is that it leads to the exact results for the *noncritical* characteristics of low-dimensional magnets at low temperatures. In particular, the physically expected limiting value of the antiferromagnetic susceptibility at  $T \rightarrow 0$  and  $H = 0$  is exactly recovered and the singularity of  $\chi(H, T)$  at  $H, T \rightarrow 0$  is entirely explained in the 1-st order in  $1/D$ . The latter it is unlikely to be essentially changed in the next orders in  $1/D$ . All the examples considered up to now suggest that the coefficients in the expansions of the noncritical quantities in powers of  $\theta$  are polynomials in  $1/D$  (see ref. [8]). If it is true, then the up to now not available low-temperature

expansions of these quantities can be obtained with the help of the  $1/D$  expansion! Further it should imply that there is some method of derivation of these low-temperature expansions without using the  $1/D$  expansion. The search for such a method is planned for the nearest future.

It would be very interesting to compare the results of the  $1/D$  expansion with results obtained by other methods. In particular, for the energy of a square-lattice classical Heisenberg magnet the MC simulations were made by Shenker and Tobochnik [11] (see the comparison in ref. [8]), but the antiferromagnetic susceptibility was simulated by various researches only for a quantum model with  $S = 1/2$ . As concerns the 2-dimensional model with  $D = 2$ , the  $1/D$  expansion cannot, naturally, describe the Kosterlitz–Thouless transition, which occurs in this system. But one can expect that the general features of the temperature dependence of the antiferromagnetic susceptibility in magnetic fields described by the  $1/D$  expansion are inherent in this model, too. Moreover, in the magnetic field the behavior of the antiferromagnetic model with  $D = 2$  should simplify, because the magnetic field lifts the spontaneous symmetry breaking and induces the gap of spin fluctuations. In this case at low temperatures it is enough to take into account only the lowest order diagram of the spin-wave theory that is naturally contained in the  $1/D$  expansion in the 1-st order in  $1/D$  (comp. (4.12)). It should be stressed that for the model with  $D = 2$  the effects in the temperature and field dependence of the antiferromagnetic susceptibility discussed in this paper should be the most strongly revealed. For the Heisenberg ( $D = 3$ ) antiferromagnet the behavior in the magnetic field can be more complicated, than for  $D = 2$ . As we have seen, at low temperatures even small magnetic field forces the spins to lie perpendicular to it. This decreases the effective number of spin components from  $D = 3$  to  $D = 2$  and should lead to the Kosterlitz–Thouless transition with disappearance of the gap. But it should not change essentially the results for the susceptibility in this region, since in the expression for the  $1/D$  correction to the magnetization (4.8) enters the gap of the out-of-plane spin waves, which cannot disappear due to the Kosterlitz–Thouless transition.

It should be also mentioned that the  $D$ -component vector model [9] considered in this article can be generalized for hamiltonians with the spin anisotropy. For example, one can consider the so-called  $n-D$  model [10], in which only  $n$  from the total  $D$  spin components are coupled by the exchange interaction. In this sense the  $x-y$  model ( $D = 3, n = 2$ ) is something different from the plane rotator model ( $D = n = 2$ ). It should be noted that the quantities  $n$  and  $D$  play the different roles: the well-known expansion of the critical indices of 3-dimensional systems is the expansion in  $1/n$ , and the expansion developed here for low-dimensional systems is the  $1/D$  expansion. The results of the present article can be generalized for the  $n-D$  model, as well as for more general models with anisotropic spin interactions.

## Appendix

### The 1/D diagrams

The additional diagrams constituting  $\hat{\Lambda}_{\alpha\alpha}^{(1/D)}(\mathbf{k})$  in the expression for the compact part of the transverse spin-spin correlation function  $\tilde{\Lambda}_{\alpha\alpha}(\mathbf{k})$  (2.4) represented in fig.2 have the following analytical form:

$$\begin{aligned}
\hat{\Lambda}_{\alpha\alpha}^{(1)} &= \tilde{\Lambda}_{\alpha\alpha z z} l_z \equiv \tilde{\Lambda}_{\alpha\alpha z z} \frac{1}{2} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \beta \tilde{J}_{z\mathbf{q}} \\
\hat{\Lambda}_{\alpha\alpha}^{(2)} &= \frac{1}{2} \tilde{\Lambda}_{\alpha\alpha\beta\beta\gamma\gamma} \tilde{\Lambda}_{\beta\beta\gamma\gamma} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} V_{\mathbf{q}} \tilde{V}_{\mathbf{q}} \\
\hat{\Lambda}_{\alpha\alpha}^{(3)} &= \tilde{\Lambda}_{\alpha\alpha\beta\beta z} \tilde{\Lambda}_{\beta\beta z} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \beta \tilde{J}_{z\mathbf{q}} \tilde{V}_{\mathbf{q}} \\
\hat{\Lambda}_{\alpha\alpha}^{(4)} &= \frac{1}{2} \tilde{\Lambda}_{\alpha\alpha\beta\beta\gamma\gamma} \tilde{\Lambda}_{\beta\beta z} \tilde{\Lambda}_{\gamma\gamma z} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \beta \tilde{J}_{z\mathbf{q}} \tilde{V}_{\mathbf{q}}^2 \\
\hat{\Lambda}_{\alpha\alpha}^{(5)}(\mathbf{k}) &= \tilde{\Lambda}_{\alpha\alpha\beta\beta}^2 v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \beta \tilde{J}_{\mathbf{k}-\mathbf{q}} \tilde{V}_{\mathbf{q}} \\
\hat{\Lambda}_{\alpha\alpha}^{(6)}(\mathbf{k}) &= \tilde{\Lambda}_{\alpha\alpha z}^2 v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \beta \tilde{J}_{\mathbf{k}-\mathbf{q}} \beta \tilde{J}_{z\mathbf{q}} \\
\hat{\Lambda}_{\alpha\alpha}^{(7+7')}(\mathbf{k}) &= 2 \tilde{\Lambda}_{\alpha\alpha\beta\beta} \tilde{\Lambda}_{\alpha\alpha z} \tilde{\Lambda}_{\beta\beta z} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \beta \tilde{J}_{\mathbf{k}-\mathbf{q}} \beta \tilde{J}_{z\mathbf{q}} \tilde{V}_{\mathbf{q}} \\
\hat{\Lambda}_{\alpha\alpha}^{(8)}(\mathbf{k}) &= \tilde{\Lambda}_{\alpha\alpha\beta\beta} \tilde{\Lambda}_{\alpha\alpha\gamma\gamma} \tilde{\Lambda}_{\beta\beta z} \tilde{\Lambda}_{\gamma\gamma z} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \beta \tilde{J}_{\mathbf{k}-\mathbf{q}} \beta \tilde{J}_{z\mathbf{q}} \tilde{V}_{\mathbf{q}}^2
\end{aligned} \tag{A.1}$$

Here  $\tilde{\Lambda}_{\alpha\alpha\beta\beta} = \tilde{\Lambda}_{\beta\beta\gamma\gamma}$ ,  $\tilde{\Lambda}_{\alpha\alpha z} = \tilde{\Lambda}_{\beta\beta z}$ , etc., are the renormalized multi-spin cumulants with  $\alpha \neq \beta \neq \gamma$  (no summation over  $\beta$  and  $\gamma$  in (A.1)) given by the formulas analogous to (2.5). As the diagrams (A.1) should be calculated only in the 1-st nonvanishing order in  $1/D$ , one can use for the renormalized transverse interaction line  $\beta \tilde{J}_{\mathbf{q}}$  (see fig.1,c) the simplified expression  $\beta \tilde{J}_{\mathbf{q}} \cong \beta J_{\mathbf{q}} / (1 - \tilde{\Lambda}_{\alpha\alpha} \beta J_{\mathbf{q}})$ , where  $\tilde{\Lambda}_{\alpha\alpha} = (\theta/D)G$  and  $G$  corresponds to the spherical model (see (2.20)). The renormalized longitudinal interaction  $\beta \tilde{J}_{z\mathbf{q}}$

(see fig.2,b) is given by

$$\beta\tilde{J}_{z\mathbf{q}} = \frac{\beta J_{\mathbf{q}}}{1 - (\tilde{\Lambda}_{zz} + \tilde{\Lambda}_{\alpha\alpha z}^2 \tilde{V}_{\mathbf{q}})\beta J_{\mathbf{q}}} \quad (\text{A.2})$$

and the renormalized 4-spin correlation line  $\tilde{V}_{\mathbf{q}}$  (see fig.2,c) reads  $\tilde{V}_{\mathbf{q}} = V_{\mathbf{q}}/(1 - \tilde{\Lambda}_{\alpha\alpha\beta\beta} V_{\mathbf{q}})$ , where

$$V_{\mathbf{q}} = \frac{D}{2} v_0 \int \frac{d\mathbf{p}}{(2\pi)^d} \beta\tilde{J}_{\mathbf{p}} \beta\tilde{J}_{\mathbf{q}-\mathbf{p}} \quad (\text{A.3})$$

is the unrenormalized 4-spin correlation line, the factor  $D$  (or  $D-1$ , which plays no role here) in (A.3) resulting from the summation over the spin-component indices  $\beta$  and  $\gamma$  in the diagrams. Calculating now the renormalized cumulants  $\tilde{\Lambda}$  in (A.1) in the lowest order in  $1/D$  by the pass method, one gets [8]

$$\tilde{\Lambda}_{\alpha\alpha\beta\beta} \cong -\left(\frac{2}{D}\right)^3 \frac{1}{(2y)^2(2y-1)}; \quad \tilde{\Lambda}_{\alpha\alpha\beta\beta\gamma\gamma} \cong \left(\frac{2}{D}\right)^5 \frac{2(3y-1)}{(2y)^3(2y-1)^3} \quad (\text{A.4})$$

with  $y \equiv 1/(\theta G)$  and, additionally,

$$\begin{aligned} \tilde{\Lambda}_{zz} &\cong \tilde{\Lambda}_{\alpha\alpha} + \tilde{\Lambda}_{\alpha\alpha\beta\beta}\xi^2; & \tilde{\Lambda}_{\alpha\alpha z} &\cong \tilde{\Lambda}_{\alpha\alpha\beta\beta}\xi \\ \tilde{\Lambda}_{\alpha\alpha z z} &\cong \tilde{\Lambda}_{\alpha\alpha\beta\beta} + \tilde{\Lambda}_{\alpha\alpha\beta\beta\gamma\gamma}\xi^2; & \tilde{\Lambda}_{\alpha\alpha\beta\beta z} &\cong \tilde{\Lambda}_{\alpha\alpha\beta\beta\gamma\gamma}\xi \end{aligned} \quad (\text{A.5})$$

where  $\xi = (D/\theta)(h + \nu m_0) = Dym_0$ . With the use of these results for the corresponding contributions into  $\Delta_{\mathbf{k}}^{(1/D)} \equiv \lim_{D \rightarrow \infty} [(D^2/\theta)\hat{\Lambda}_{\alpha\alpha}^{(1/D)}(\mathbf{k})]$ , one obtains

$$\begin{aligned} \Delta_{\alpha\alpha}^{(1)} &= -\frac{\nu G^2}{(2y-1)} \left[ 1 - 4m_0^2 y \frac{3y-1}{(2y-1)^2} \right] v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \tilde{\lambda}_{z\mathbf{q}} \\ \Delta_{\alpha\alpha}^{(2)} &= -2G^5 \frac{3y-1}{(2y-1)^4} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \varphi_{\mathbf{q}} \tilde{\varphi}_{\mathbf{q}} \\ \Delta_{\alpha\alpha}^{(3)} &= -8\nu m_0^2 y G^4 \frac{3y-1}{(2y-1)^4} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \tilde{\lambda}_{z\mathbf{q}} \tilde{\varphi}_{\mathbf{q}} \\ \Delta_{\alpha\alpha}^{(4)} &= 4\nu m_0^2 y G^6 \frac{3y-1}{(2y-1)^5} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \tilde{\lambda}_{z\mathbf{q}} \tilde{\varphi}_{\mathbf{q}}^2 \\ \Delta_{\alpha\alpha}^{(5)}(\mathbf{k}) &= \frac{2\nu G^4}{(2y-1)} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \tilde{\lambda}_{\mathbf{k}-\mathbf{q}} \tilde{\varphi}_{\mathbf{q}} \\ \Delta_{\alpha\alpha}^{(6+7+7'+8)}(\mathbf{k}) &= \frac{4m_0^2 y G^3}{(2y-1)^2} v_0 \int \frac{d\mathbf{q}}{(2\pi)^d} \tilde{\lambda}_{\mathbf{k}-\mathbf{q}} \tilde{\lambda}_{z\mathbf{q}} L_{\mathbf{q}}^2 \end{aligned} \quad (\text{A.6})$$

where  $\tilde{\varphi}_{\mathbf{q}} \equiv \varphi_{\mathbf{q}} L_{\mathbf{q}} \equiv \varphi_{\mathbf{q}}/(1 + a\varphi_{\mathbf{q}})$ ,  $a \equiv G^2/(2y-1)$ ,

$$\varphi_{\mathbf{q}} = v_0 \int \frac{d\mathbf{p}}{(2\pi)^d} \tilde{\lambda}_{\mathbf{p}} \tilde{\lambda}_{\mathbf{p}-\mathbf{q}}; \quad \tilde{\lambda}_{\mathbf{q}} \equiv \tilde{J}_{\mathbf{q}}/J_0 \equiv \frac{\lambda_{\mathbf{q}}}{1 - \nu G \lambda_{\mathbf{q}}} \quad (\text{A.7})$$

The expression for the renormalized  $z$ -interaction line  $\tilde{\lambda}_{z\mathbf{q}} \equiv \tilde{J}_{z\mathbf{q}}/J_0$  can be written in the form

$$\tilde{\lambda}_{z\mathbf{q}} = \frac{\lambda_{\mathbf{q}}}{1 - \nu G_{z\mathbf{q}} \lambda_{\mathbf{q}}}; \quad G_{z\mathbf{q}} = G \left( 1 - \frac{2m_0^2 y}{2y - 1} L_{\mathbf{q}} \right) \quad (\text{A.8})$$

Further simplifications leading to the results listed at the end of the Section 2 can be achieved if one expresses  $\varphi_{\mathbf{q}}$  through  $r_{\mathbf{q}}$  (2.32) with the use of the relation  $(2y - 1)(1 + a\varphi_{\mathbf{q}}) = r_{\mathbf{q}} + 2m_0^2 y$ .
